Package 'sem'

August 29, 2013

Version 3.1-3

Date 2013/04/09

Title Structural Equation Models

Depends R (>= 2.14.0), stats, MASS, matrixcalc

Suggests boot, tcltk, polycor, MBESS, mi

LazyLoad yes

LazyData yes

ByteCompile yes

Description This package contains functions for fitting general linear
structural equation models (with observed and unobserved
variables) using the RAM approach, and for fitting structural
equations in observed-variable models by two-stage least squares.

Bollen   *Bollen's Data on Industrialization and Political Democracy*

Description

This data set includes four measures of democracy at two points in time, 1960 and 1965, and three
measures of industrialization in 1960, for 75 developing countries.

Usage

```
Bollen
```

Format

A data frame with 75 observations on the following 11 variables.

y1 freedom of the press, 1960

y2 freedom of political opposition, 1960

y3 fairness of elections, 1960

y4 effectivness of elected legislature, 1960

y5 freedom of the press, 1965

y6 freedom of political opposition, 1965

y7 fairness of elections, 1965

y8 effectivness of elected legislature, 1965

x1 GNP per capita, 1960

x2 energy consumption per capita, 1960

x3 percentage of labor force in industry, 1960

Details

Variables y1 through y4 are intended to be indicators of the latent variable *political democracy in 1960*; y5 through y8 indicators of *political democracy in 1965*; and x1 through x3 indicators of *industrialization in 1960*.

bootSem   *Bootstrap a Structural Equation Model*

Description

Bootstraps a structural equation model in an sem object (as returned by the sem function).

Usage

```
bootSem(model, ...)

## S3 method for class 'sem'
bootSem(model, R=100, Cov=cov, data=model$data, max.failures=10, ...)

## S3 method for class 'msem'
bootSem(model, R=100, Cov=cov, data=model$data, max.failures=10, ...)

## S3 method for class 'bootsem'
print(x, digits=getOption("digits"), ...)

## S3 method for class 'bootsem'
summary(object,
    type=c("perc", "bca", "norm", "basic", "none"), level=0.95, ...)
```

Arguments

model	an sem or msem object, produced by the sem function.
R	the number of bootstrap replications; the default is 100, which should be enough for computing standard errors, but not confidence intervals (except for the normal-theory intervals).
Cov	a function to compute the input covariance or moment matrix; the default is cov. Use cor if the model is fit to the correlation matrix. The function hetcor in the polycor package will compute product-moment, polychoric, and poly-serial correlations among mixed continuous and ordinal variables (see the first example below for an illustration).
data	in the case of a sem (i.e., single-group) model, a data set in a form suitable for Cov; for example, for the default Cov=cov, data may be a numeric data frame or a numeric matrix. In the case of an msem (i.e., multi-group) model, a list of data sets (again in the appropriate form), one for each group; in this case, bootstrapping is done within each group, treating the groups as strata. Note that the original observations are required, not just the covariance matrix of the observed variables in the model. The default is the data set stored in the sem object, which will be present only if the model was fit to a data set rather than to a covariance or moment matrix, and may not be in a form suitable for Cov.
max.failures	maximum number of consecutive convergence failures before bootSem gives up.
x, object	an object of class bootsem.
digits	controls the number of digits to print.
type	type of bootstrapped confidence intervals to compute; the default is "perc" (per-centile); see boot.ci for details.
level	level for confidence intervals; default is 0.95.
...	in bootSem, arguments to be passed to sem; otherwise ignored.

Details

bootSem implements the nonparametric bootstrap, assuming an independent random sample. Convergence failures in the bootstrap resamples are discarded (and a warning printed); more than max.failures consecutive convergence failures (default, 10) result in an error. You can use the boot function in the **boot** package for more complex sampling schemes and additional options.

Bootstrapping is implemented by resampling the observations in data, recalculating the input co-variance matrix with Cov, and refitting the model with sem, using the parameter estimates from the original sample as start-values.

Warning: the bootstrapping process can be very time-consuming.

Value

bootSem returns an object of class bootsem, which inherits from class boot, supported by the **boot** package. The returned object contains the following components:

t0	the estimated parameters in the model fit to the original data set.

t	a matrix containing the bootstrapped estimates, one bootstrap replication per row.
data	the data to which the model was fit.
seed	the value of .Random.seed when bootSem was called.
statistic	the function used to produce the bootstrap replications; this is always the local function refit from bootSem.
sim	always set to "ordinary"; see the documentation for the boot function.
stype	always set to "i"; see the documentation for the boot function.
call	the call of the bootSem function.
weights	a vector of length equal to the number of observations N, with entries $1/N$. For a multi-group model, the weights in group j are $1/N_j$, the inverse of the number of observations in the group.
strata	a vector of length N containing the number of the stratum to which each observation belongs; for a single-group model, all entries are 1.

CNES   *Variables from the 1997 Canadian National Election Study*

Description

These variables are from the mailback questionnaire to the 1997 Canadian National Election Study, and are intended to tap attitude towards "traditional values."

Usage

```
CNES
```

Format

A data frame with 1529 observations on the following 4 variables.

MBSA2 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, "We should be more tolerant of people who choose to live according to their own standards, even if they are very different from our own."

MBSA7 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, "Newer lifestyles are contributing to the breakdown of our society."

MBSA8 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, "The world is always changing and we should adapt our view of moral behaviour to these changes."

MBSA9 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, "This country would have many fewer problems if there were more emphasis on traditional family values."

effects.sem   *Total, Direct, and Indirect Effects for Structural Equation Models*

Description

The sem method for the standard generic function effects computes total, direct, and indirect effects for a fitted structural equation model according to the method described in Fox (1980).

Usage

```
## S3 method for class 'sem'
effects(object, ...)
## S3 method for class 'msem'
effects(object, ...)

## S3 method for class 'semeffects'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'semeffectsList'
print(x, digits = getOption("digits"), ...)
```

Arguments

`object`	a fitted structural-equation model object produced by the [sem](#) function.
`x`	an object of class `semeffects` or `semeffectsList`, produced by `effects`.
`digits`	digits to print.
`...`	not used.

Value

`effect.sem` returns an object of class `semeffects` with `Total`, `Direct`, and `Indirect` elements.

fscores   *Factor Scores for Latent Variables*

Description

Calculate factor scores or factor-score coefficients for the latent variables in a structural-equation model.

Usage

```
## S3 method for class 'sem'
fscores(model, data=model$data, center=TRUE, scale=FALSE, ...)
## S3 method for class 'msem'
fscores(model, data=model$data, center=TRUE, scale=FALSE, ...)
```

Arguments

model   an object of class "sem" or "msem", produced by the [sem](#) function.

data   an optional numeric data frame or matrix containing the observed variables in
            the model; if not NULL, the estimated factor scores are returned; if NULL, the
            factor-score *coefficients* are returned. The default is the data element of model,
            which is non-NULL if the model was fit to a data set rather than a covariance or
            moment matrix.

center   if TRUE, the default, the means of the observed variables are subtracted prior
            to computing factor scores. One would normally use this option if the model is
            estimated from a covariance or correlation matrix among the observed variables.

scale   if TRUE, the possibly centered variables are divided by their root-mean-squares;
            the default is FALSE. One would normally use this option if the model is esti-
            mated from a correlation matrix among the observed variables. Centering and
            scaling are performed by the [scale](#) function.

...   arguments to pass down.

Details

Factor-score coefficients are computed by the "regression" method as $B = C^{-1}C^*$, where C is the model-implied covariance or moment matrix among the observed variables and C^* is the matrix of model-implied covariances or moments between the observed and latent variables.

Value

Either a matrix of estimated factor scores (if the data argument is supplied) or a matrix of factor-score coefficients (otherwise). In the case of an "msem" argument, a list of matrices is returned.

information.criteria   *Additional Information Criteria*

Description

These are generic functions for computing, respectively, the AICc (second-order corrected Akaike Information Criterion) and CAIC (consistent Akaike Information Criterion).

Usage

```
AICc(object, ...)

CAIC(object, ...)
```

Arguments

object   an object for which an appropriate `AICc` or `CAIC` method exists.
...   possible additional arguments for methods.

Klein	*Klein's Data on the U. S. Economy*

Description

Data for Klein's (1950) simple econometric model of the U. S. economy.

The Klein data frame has 22 rows and 10 columns.

Usage

```
Klein
```

Format

This data frame contains the following columns:

Year 1921–1941

C consumption.

P private profits.

Wp private wages.

I investment.

K.lag capital stock, lagged one year.

X equilibrium demand.

Wg government wages.

G government non-wage spending.

T indirect business taxes and net exports.

```

Kmenta   *Partly Artificial Data on the U. S. Economy*

Description

These are partly contrived data from Kmenta (1986), constructed to illustrate estimation of a simultaneous-equation model.

The Kmenta data frame has 20 rows and 5 columns.

Usage

```
Kmenta
```

Format

This data frame contains the following columns:

Q food consumption per capita.

P ratio of food prices to general consumer prices.

D disposable income in constant dollars.

F ratio of preceding year's prices received by farmers to general consumer prices.

A time in years.

Details

The exogenous variables D, F, and A are based on real data; the endogenous variables P and Q were generated by simulation.

miSem | *Estimate a Structural Equation Model By Multiple Imputation*

Description

miSem uses the [mi](#) function in the **mi** package to generate multiple imputations of missing data, fitting the specified model to each completed data set.

Usage

```
miSem(model, ...)

## S3 method for class 'semmod'
miSem(model, ..., data, formula = ~., raw = FALSE,
    fixed.x=NULL, objective=objectiveML, n.imp=5, n.iter=30,
    seed=sample(1e+06, 1), mi.args=list())

## S3 method for class 'semmodList'
miSem(model, ..., data, formula = ~., group, raw=FALSE,
        fixed.x=NULL, objective=msemObjectiveML,
        n.imp=5, n.iter=30, seed=sample(1e6, 1), mi.args=list())

## S3 method for class 'miSem'
print(x, ...)

## S3 method for class 'miSem'
summary(object, digits=max(3, getOption("digits") - 2), ...)
```

Arguments

model	an SEM model-description object of class semmod or semmodList, created by [specifyEquations cfa](#), or [specifyModel](#), in the case of a multi-group model in combination with [multigroupModel](#).
..., formula, raw, fixed.x, objective, group	
	arguments to be passed to [sem](#).
data	an R data frame, presumably with some missing data (encoded as NA), containing the data for fitting the SEM, possibly along with other variables to use to obtain multiple imputations of missing values. In the case of a multi-group model, this must be a *single* data frame.
n.imp	number of imputations (default 5).
n.iter	number of iterations for the multiple-imputation process (default 30).
seed	seed for the random-number generator (default is an integer sampled from 1 to 1E6); stored in the resulting object.
mi.args	other arguments to be passed to [mi](#).
x, object	an object of class "miSem".
digits	for printing numbers.

Value

`miSem` returns an object of class `"miSem"` with the following components:

initial.fit	an sem model object produced using objectiveFIML if raw=TRUE, or the objective function given by the objective argument otherwise.
mi.fits	a list of sem model objects, one for each imputed data set.
imputation	the object produced by mi, containing the imputed data sets.
seed	the seed used for the random number generator.

ML.methods	*Methods for sem Objects Fit Using the* objectiveML, objectiveGLS, objectiveFIML, msemObjectiveML, *and* msemObjectiveGLS *Objective Functions*

Description

These functions are for objects fit by sem using the objectiveML (multivariate-normal full-information maximum-likelihood), link{objectiveFIML} (multivariate-normal full-information maximum-likihood in the presence of missing data), objectiveGLS (generalized least squares), and msemObjectiveML (multigroup multivariate-normal FIML) objective functions.

Usage

```
## S3 method for class 'objectiveML'
anova(object, model.2, robust=FALSE, ...)
## S3 method for class 'objectiveFIML'
anova(object, model.2, ...)

## S3 method for class 'objectiveML'
logLik(object, ...)
## S3 method for class 'objectiveFIML'
logLik(object, saturated=FALSE, intercept="Intercept", iterlim=1000, ...)
## S3 method for class 'objectiveML'
deviance(object, ...)
## S3 method for class 'objectiveFIML'
deviance(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
deviance(object, ...)
## S3 method for class 'objectiveML'
AIC(object, ..., k)
## S3 method for class 'objectiveFIML'
AIC(object, saturated.logLik, ..., k)
## S3 method for class 'msemObjectiveML'
AIC(object, ..., k)
## S3 method for class 'objectiveML'
AICc(object, ...)
## S3 method for class 'objectiveFIML'
AICc(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
AICc(object, ...)
```

```
## S3 method for class 'objectiveML'
BIC(object, ...)
## S3 method for class 'objectiveFIML'
BIC(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
BIC(object, ...)
## S3 method for class 'objectiveML'
CAIC(object, ...)
## S3 method for class 'objectiveFIML'
CAIC(object, saturated.logLik, ...)

## S3 method for class 'objectiveML'
print(x, ...)
## S3 method for class 'objectiveGLS'
print(x, ...)
## S3 method for class 'objectiveFIML'
print(x, saturated=FALSE, ...)

## S3 method for class 'msemObjectiveML'
summary(object, digits=getOption("digits"), conf.level=.90, robust=FALSE,
    analytic.se=object$t <= 500,
    fit.indices=c("GFI", "AGFI", "RMSEA", "NFI", "NNFI", "CFI", "RNI", "IFI", "SRMR", "AIC", "AICc"
## S3 method for class 'msemObjectiveGLS'
summary(object, digits=getOption("digits"), conf.level=.90,
    fit.indices=c("GFI", "AGFI", "RMSEA", "NFI", "NNFI", "CFI", "RNI", "IFI", "SRMR"), ...)
```

Arguments

`object, model.2, x`

an object inheriting from class objectiveML, objectiveGLS, objectiveFIML, msemObjectiveML, or msemObjectiveGLS.

`robust`   if TRUE, compute robust standard errors or test.

`fit.indices`   a character vector of "fit indices" to report; the allowable values are those given in **Usage** above, and vary by the objective function. If the argument isn't given

then the fit indices reported are taken from the R `fit.indices` option; if this option isn't set, then only the AIC and BIC are reported for models fit with `objectiveML`, `objectiveFIML`, or `msemObjectiveML`, and no fit indices are reported for models fit with `objectiveGLS` or `msemObjectiveGLS`.

k, ...   ignored.

digits   digits to be printed.

conf.level   level for confidence interval for the RMSEA index (default is .9).

analytic.se   use analytic (as opposed to numeric) coefficient standard errors; default is `TRUE` where analytic standard errors are available if there are no more than 100 parameters in the model and `FALSE` otherwise.

saturated   if `TRUE` (the default is `FALSE`); compute the log-likelihood (and statistics that depend on it) for the saturated model when the objective function is FIML in the presence of missing data. This can be computationally costly.

intercept   the name of the intercept regressor in the raw data, to be used in calculating the saturated log-likelihood for the FIML estimator; the default is `"Intercept"`.

saturated.logLik
                   the log-likelihood for the saturated model, as returned by `logLik` with `saturated=TRUE`; if absent, this will be computed and the computation can be time-consuming.

iterlim   iteration limit used by the `nlm` optimizer to compute the saturated log-likelihood for the FIML estimator with missing data; defaults to `1000`.

modIndices   *Modification Indices for Structural Equation Models*

Description

`mod.indices` calculates modification indices (score tests) and estimated parameter changes for the fixed and constrained parameters in a structural equation model fit by multinormal maximum likelihood.

Usage

```
## S3 method for class 'objectiveML'
modIndices(model, duplicated, deviance=NULL, ...)
## S3 method for class 'msemObjectiveML'
modIndices(model, ...)

## S3 method for class 'modIndices'
print(x, n.largest=5, ...)
## S3 method for class 'msemModIndices'
print(x, ...)

## S3 method for class 'modIndices'
summary(object, round=2,
    print.matrices=c("both", "par.change", "mod.indices"), ...)
## S3 method for class 'msemModIndices'
summary(object, ...)
```

Arguments

model	an object of class objectiveML or msemObjectiveML, produced by the [sem](#) function.
object, x	an object of class modIndices or msemModIndices, produced by the modIndices function.
n.largest	number of modification indices to print in each of the A and P matrices of the RAM model.
round	number of places to the right of the decimal point in printing modification indices.
print.matrices	which matrices to print: estimated changes in the fixed parameters, modification indices, or both (the default).
duplicated, deviance	for internal use.
...	arguments to be passed down.

Details

Modification indices are one-df chi-square score ("Lagrange-multiplier") test statistics for the fixed and constrained parameters in a structural equation model. They may be regarded as an estimate of the improvement in the likelihood-ratio chi-square statistic for the model if the corresponding parameter is respecified as a free parameter. The modIndices function also estimates the change in the value of a fixed or constrained parameter if the parameter is respecified as free. When several parameters are set equal, modification indices and estimated changes are given for all but the first. Modification indices and estimated parameter changes for currently free parameters are given as NA.

The method employed is described in Saris, Satorra, and Sorbom (1987) and Sorbom (1989).

Value

modIndices returns an object of class modIndices with the following elements:

mod.A	modification indices for the elements of the A matrix.
mod.P	modification indices for the elements of the P matrix.
par.A	estimated parameter changes for the elements of the A matrix.
par.P	estimated parameter changes for the elements of the P matrix.

objective.functions   *sem Objective-Function Builders*

Description

These functions return objective functions suitable for use with optimizers called by sem. The user would not normally call these functions directly, but rather supply one of them in the objective argument to sem. Users may also write their own objective functions. objectiveML and objectiveML2 are for multinormal maximum-likelihood estimation; objectiveGLS and objectiveGLS2 are for generalized least squares; and objectiveFIML2 is for so-called "full-information maximum-likelihood" estimation in the presence of missing data. The FIML estimator provides the same estimates as the ML estimator when there is no missing data; it can be slow because it iterates over the unique patterns of missing data that occur in the data set. objectiveML and objectiveGLS use compiled code and are therefore substantially faster. objectiveML2 and objectiveGLS2 are provided primarily to illustrate how to write sem objective functions in R. msemObjectiveML uses compiled code is for fitting multi-group models by multinormal maximum likelihood; msemObjectiveML2 is similar but doesn't use compiled code. msemObjectiveGLS uses compiled code and is for fitting multi-group models by generalized least squares.

Usage

```
objectiveML(gradient=TRUE, hessian=FALSE)
objectiveML2(gradient=TRUE)

objectiveGLS(gradient=FALSE)
objectiveGLS2(gradient=FALSE)

objectiveFIML(gradient=TRUE, hessian=FALSE)
objectiveFIML2(gradient=TRUE, hessian=FALSE)

msemObjectiveML(gradient=TRUE)
msemObjectiveML2(gradient=TRUE)

msemObjectiveGLS(gradient=FALSE)
```

Arguments

gradient   If TRUE, the object that's returned includes a function for computing an analytic
            gradient; there is at present no analytic gradient available for objectiveFIML,
            objectiveGLS, objectiveGLS2, or msemObjectiveGL.

hessian   If TRUE, the objected returned includes a function to compute an analytic Hes-
            sian; only avaiable for objectiveML and not generally recommended.

Value

These functions return an object of class "semObjective", with up to two elements:

objective   an objective function.

gradient   a gradient function.

optimizers   *sem Optimizers*

Description

The default optimizer used by [sem](#) is optimizerSem, which employs compiled code and is integrated with the [objectiveML](#) and [objectiveGLS](#) objective functions; optimizerSem, written by Zhenghua Nie, is a modified version of the standard R nlm optimizer, which was written by Saikat DebRoy, R-core, and Richard H. Jones. The other functions call optimizers ([nlm](#), [optim](#), or [nlminb](#)), to fit structural equation models, and are called by the [sem](#) function. The user would not normally call these functions directly, but rather supply one of them in the optimizer argument to sem. Users may also write them own optimizer functions. msemOptimizerNlm is for fitting multigroup models, and also adapts the nlm code.

Usage

```
optimizerSem(start, objective=objectiveML,
gradient=TRUE, maxiter, debug, par.size, model.description, warn, ...)

optimizerMsem(start, objective=msemObjectiveML, gradient=TRUE,
maxiter, debug, par.size, model.description, warn=FALSE, ...)

optimizerNlm(start, objective=objectiveML, gradient=TRUE,
maxiter, debug, par.size, model.description, warn, ...)

optimizerOptim(start, objective=objectiveML, gradient=TRUE,
maxiter, debug, par.size, model.description, warn, method="CG", ...)

optimizerNlminb(start, objective=objectiveML, gradient=TRUE, maxiter,
debug, par.size, model.description, warn, ...)

msemOptimizerNlm(start, objective=msemObjectiveML, gradient=TRUE,
maxiter, debug, par.size, model.description, warn=FALSE, ...)
```

Arguments

start	a vector of start values for the parameters.
objective	the objective function to be optimized; see [objective.functions](#).
gradient	TRUE if an analytic gradient is to be used (if one is available).
maxiter	the maximum number of iterations allowed.
debug	TRUE to show the iteration history and other available information about the optimization.
par.size	"startvalues" to have the optimizer scale the problem according to the magitudes of the start values (ignored by optimizerNlminb).

model.description

    a list with elements describing the structural-equation model (see the code for details).

warn   if FALSE, suppress warnings during the optimization.

method   the method to be employed by the [optim](#) optimizer; the default is "CG" (conjugate-gradient).

...   additional arguments for the nlm, optim, or nlminb optimizer.

Value

An object of class "semResult", with elements:

convergence   TRUE if the optimization apparently converged.

iterations   the number of iterations required.

par   the vector of parameter estimates.

vcov   the estimated covariance matrix of the parameter estimates, based on a numeric Hessian; not supplied by optimizerNlminb.

criterion   the optimized value of the objective function.

C   the model-implied covariance or moment matrix at the parameter estimates.

A   the estimated A matrix.

P   the estimated P matrix.

Author(s)

John Fox <jfox@mcmaster.ca>, and Zhenghua Nie, in part adapting work by Saikat DebRoy, R-core, and Richard H. Jones.

pathDiagram   *Draw Path Diagram*

Description

pathDiagram creates a description of the path diagram for a structural-equation-model or SEM-specification object to be processed by the graph-drawing program *dot*, which can be called automatically; see Koutsofios and North (2002) and <http://www.graphviz.org/>. To obtain graphics output directly, the *dot* program must be on the system search path. The semmod method sets up a call to the sem method.

Usage

```
## S3 method for class 'sem'
pathDiagram(model, file, min.rank=NULL, max.rank=NULL,
same.rank=NULL, variables=model$var.names, parameters,
ignore.double=TRUE, edge.labels=c("names", "values", "both"),
size=c(8, 8), node.font=c("Helvetica", 14),
edge.font=c("Helvetica", 10), rank.direction=c("LR", "TB"),
digits=2, standardize=FALSE, output.type=c("graphics", "dot"),
graphics.fmt="pdf", dot.options=NULL, ...)

## S3 method for class 'semmod'
pathDiagram(model, obs.variables, ...)
```

Arguments

model	a structural-equation-model or SEM-specification object produced by sem, or, respectively, specifyEquations, specifyModel, or cfa.
...	arguments passed down, e.g., from the semmod method to the sem method.
file	a file name, given *without* an extension, to which to write the *dot* description of the path diagram and, by default, to use that to draw a graph of the model; if not specified, the *dot* description is written to standard output (normally the R Console). Note that by default (see the output.type argument below), *two* files are written: a ".dot" file and a graphics file of type specified by the graphics.fmt argument (below); file may include a path specification.
min.rank	a character string listing names of variables to be assigned minimum rank (order) in the graph; the names should be separated by commas.
max.rank	a character string listing names of variables to be assigned maximum rank in the graph; the names should be separated by commas.
same.rank	a character string or vector of character strings of variables to be assigned equivalent rank in the graph; names in each string should be separated by commas.
variables	variable names; defaults to the variable names in model. If specified, the variable names should be in the same order as in model.
parameters	parameter names; defaults to the parameter names in model. If specified, the parameter names should be in the same order as in model.
ignore.double	if TRUE, the default, double-headed arrows, representing variances and covariances, are not graphed.
edge.labels	"names" to label arrows with parameter names; "values" to label arrows with parameter estimates, or "both".
size	the size of the graph, in inches.
node.font	font name and point-size for printing variable names.
edge.font	font name and point-size for printing arrow names or values.
rank.direction	draw graph left-to-right, "LR", the default, or top-to-bottom, "TB".
digits	number of digits after the decimal point (default, 2) to which to round parameter estimates.

standardize   if TRUE, display standardized coefficients; default is FALSE.

output.type   if ″graphics″, the default, *both* a ".dot" file and a graphics file will be created.

graphics.fmt   a graphics format recognized by the *dot* program; the default is ″pdf″; graphics.fmt is also used for the extension of the graphics file that is created.

dot.options   options to be passed to the *dot* program, given as a character string.

obs.variables   a character vector with the names of the observed variables in the model.

Value

NULL: pathDiagram is used for its side-effect, producing a graph description of the model.

ram   *RAM Matrix for a Structural-Equation Model*

Description

Print the labelled RAM definition matrix for a structural-equation model fit by sem.

Usage

```
ram(object, digits=getOption("digits"), startvalues=FALSE)
```

Arguments

object	an object of class sem returned by the sem function.
digits	number of digits for printed output.
startvalues	if TRUE, start values for parameters are printed; otherwise, the parameter estimates are printed; the default is FALSE.

Value

A data frame containing the labelled RAM definition matrix, which is normally just printed.

Author(s)

John Fox <jfox@mcmaster.ca>

ram(sem.dhp)

## End(Not run)
```

---

rawMoments   *Compute Raw Moments Matrix*

Description

Computes the "uncorrected" sum-of-squares-and-products matrix divided by the number of observations.

Usage

```
## S3 method for class 'formula'
rawMoments(formula, data, subset, na.action,
    contrasts=NULL, ...)

## Default S3 method:
rawMoments(object, na.rm=FALSE, ...)

cov2raw(cov, mean, N, sd)

## S3 method for class 'rawmoments'
print(x, ...)
```

Arguments

`object`	a one-sided model formula or an object coercible to a numeric matrix.
`formula`	a one-sided model formula specifying the model matrix for which raw moments are to be computed; note that a constant is included if it is not explicitly suppressed by putting `-1` in the formula.
`data`	an optional data frame containing the variables in the formula. By default the variables are taken from the environment from which `rawMoments` is called.
`subset`	an optional vector specifying a subset of observations to be used in computing moments.
`na.action`	a function that indicates what should happen when the data contain NAs. The default is set by the `na.action` option.
`contrasts`	an optional list. See the `contrasts.arg` argument of [model.matrix.default]().
`na.rm`	if `TRUE`, any data rows with missing data will be removed.
`cov`	a covariance or correlation matrix.
`mean`	a vector of means.
`N`	the number of observations on which the covariances or correlations are based.
`sd`	an optional vector of standard deviations, to be given if `cov` is a correlation matrix.
`x`	an object of class `rawmoments` to print.
`...`	arguments passed down.

Value

`rawMoments` and `cov2raw` return an object of class `rawmoments`, which is simply a matrix with an attribute `"N"` that contains the number of observations on which the moments are based.

readMoments | *Input a Covariance, Correlation, or Raw Moment Matrix*

Description

This functions makes it simpler to input covariance, correlation, and raw-moment matrices to be analyzed by the [sem](#) function. The matrix is input in lower-triangular form on as many lines as is convenient, omitting the above-diagonal elements. The elements on the diagonal may also optionally be omitted, in which case they are taken to be 1.

Usage

```
readMoments(file="", diag=TRUE,
    names=as.character(paste("X", 1:n, sep = "")))
```

Arguments

file   The (quoted) file from which to read the model specification, including the path to the file if it is not in the current directory. If "" (the default), then the specification is read from the standard input stream, and is terminated by a blank line.

diag   If TRUE (the default), then the input matrix includes diagonal elements.

names   a character vector containing the names of the variables, to label the rows and columns of the moment matrix.

Value

Returns a lower-triangular matrix (i.e., with zeroes above the main diagonal) suitable for input to sem.

residuals.sem	*Residual Covariances for a Structural Equation Model*

Description

These functions compute residual covariances, variance-standardized residual covariances, and normalized residual covariances for the observed variables in a structural-equation model fit by sem.

Usage

```
## S3 method for class 'sem'
residuals(object, ...)
## S3 method for class 'msem'
residuals(object, ...)

## S3 method for class 'sem'
standardizedResiduals(object, ...)
## S3 method for class 'msem'
standardizedResiduals(object, ...)

## S3 method for class 'objectiveML'
normalizedResiduals(object, ...)
## S3 method for class 'objectiveGLS'
normalizedResiduals(object, ...)
## S3 method for class 'msemObjectiveML'
normalizedResiduals(object, ...)
```

Arguments

object   an object inheriting from class sem or msem returned by the [sem](#) function.

...   not for the user.

Details

Residuals are defined as $S - C$, where S is the sample covariance matrix of the observed variables and C is the model-reproduced covariance matrix. The *standardized* residual covariance for a pair

of variables divides the residual covariance by the product of the sample standard deviations of the two variables, $(s_{ij} - c_{ij})/(s_{ii}s_{jj})^{1/2}$. The *normalized* residual is given by

$$\frac{s_{ij} - c_{ij}}{[(c_{ii}c_{jj} - c_{ij}^2)/N^*]^{1/2}}$$

where N^* is the number of observations minus one if the model is fit to a covariance matrix, or the number of observations if it is fit to a raw moment matrix.

Value

Each function returns a matrix of residuals.

sem   *General Structural Equation Models*

Description

sem fits general structural equation models (with both observed and unobserved variables). Observed variables are also called *indicators* or *manifest variables*; unobserved variables are also called *factors* or *latent variables*. Normally, the generic function (sem) is called directly with a semmod first argument produced by specifyModel, specifyEquations, or cfa, invoking the

sem.semmod method, which in turn sets up a call to the sem.default method; thus, the user may
wish to specify arguments accepted by the semmod and default methods. Similarly, for a multi-
group model, sem would normally be called with a semmodList object produced by multigroupModel
as its first argument, and would then generate a call to the code msemmod method.

Usage

```
## S3 method for class 'semmod'
sem(model, S, N, data,
     raw=identical(na.action, na.pass), obs.variables=rownames(S),
    fixed.x=NULL, formula= ~ ., na.action=na.omit, robust=!missing(data), debug=FALSE,
     optimizer=optimizerSem, objective=objectiveML, ...)

## Default S3 method:
sem(model, S, N, raw=FALSE, data=NULL, start.fn=startvalues,
     pattern.number=NULL, valid.data.patterns=NULL,
     use.means=TRUE, param.names,
    var.names, fixed.x=NULL, robust=!is.null(data), semmod=NULL, debug=FALSE,
analytic.gradient=!identical(objective, objectiveFIML),
        warn=FALSE, maxiter=1000, par.size=c("ones", "startvalues"),
start.tol=1E-6, optimizer=optimizerSem, objective=objectiveML, cls, ...)

## S3 method for class 'semmodList'
sem(model, S, N, data, raw=FALSE, fixed.x=NULL,
robust=!missing(data), formula, group="Group", debug=FALSE, ...)

## S3 method for class 'msemmod'
sem(model, S, N, start.fn=startvalues,
        group="Group", groups=names(model), raw=FALSE, fixed.x,
param.names, var.names, debug=FALSE, analytic.gradient=TRUE, warn=FALSE,
maxiter=5000, par.size = c("ones", "startvalues"), start.tol = 1e-06,
start=c("initial.fit", "startvalues"), initial.maxiter=1000,
optimizer = optimizerMsem, objective = msemObjectiveML, ...)

startvalues(S, ram, debug=FALSE, tol=1E-6)
startvalues2(S, ram, debug=FALSE, tol=1E-6)

## S3 method for class 'sem'
coef(object, standardized=FALSE, ...)
## S3 method for class 'msem'
coef(object, ...)
## S3 method for class 'sem'
vcov(object, robust=FALSE,
analytic=inherits(object, "objectiveML") && object$t <= 500, ...)
## S3 method for class 'msem'
vcov(object, robust=FALSE, analytic=inherits(object, "msemObjectiveML") && object$t <= 500, ...)
## S3 method for class 'sem'
df.residual(object, ...)
## S3 method for class 'msem'
```

```
df.residual(object, ...)
```

Arguments

model   RAM specification, which is a simple encoding of the path diagram for the
             model. The model may be given either in symbolic form (as a semmod object,
             as returned by the [specifyModel](), [specifyEquations](), or [cfa]() function, or as a
             character matrix), invoking sem.semmod, which calls sem.default after setting
             up the model, or (less conveniently) in numeric form, invoking sem.default
             directly, which is not recommended (see **Details** below). The model argument
             may also be a multigroup-model specification, as produced by [multigroupModel]().

S   covariance matrix among observed variables; may be input as a symmetric ma-
             trix, or as a lower- or upper-triangular matrix. S may also be a raw (i.e., "un-
             corrected") moment matrix — that is, a sum-of-squares-and-products matrix
             divided by N. This form of input is useful for fitting models with intercepts,
             in which case the moment matrix should include the mean square and cross-
             products for a unit variable all of whose entries are 1; of course, the raw mean
             square for the unit variable is 1. Raw-moment matrices may be computed by
             [rawMoments](). If the ram argument is given in symbolic form, then the observed-
             variable covariance or raw-moment matrix may contain variables that do not
             appear in the model, in which case a warning is printed. S may also be a list
             of covariance or moment matrices for each group in a multigroup model. As an
             alternative to specifying S the user may supply a data frame containing the data
             for the model (see the argument data).

N   number of observations on which the covariance matrix is based; for a multi-
             group model, a vector of group Ns.

data   As a generally preferable alternative to specifying S and N, the user may supply
             a data frame containing the data to which the model is to be fit. In a multigroup
             model, the data argument may be a list of data frames or a single data frame; in
             the later event, the factor given as the group argument is used to split the data
             into groups.

start.fn   a function to compute startvalues for the free parameters of the model; two func-
             tions are supplied, startvalues and a older version, startvalues2, the first of
             which is the default.

na.action   a function to process missing data, if raw data are supplied in the data ar-
             gument. The default is na.omit, which returns only complete cases; specify
             na.action=na.pass to get FIML estimates in the presence of missing data from
             the objectiveFIML and objectiveFIML2 objective functions.

raw   TRUE if S is a raw moment matrix or if a raw moment matrix — as opposed to a
             covariance matrix — is to be computed from data; the default is FALSE unless
             the na.action argument is set to na.pass.

pattern.number, valid.data.patterns
             these arguments pass information about valid (i.e., non-missing) data patterns
             and normally would not be specified directly by the user.

use.means   When raw data are supplied and intercepts are included in the model, use the
             observed-variable means as start values for the intercepts; the default is TRUE.

obs.variables   names of observed variables, by default taken from the row names of the covariance or moment matrix S, which may be given directly or generated according to the data and formula arguments.

fixed.x   names (if the ram matrix is given in symbolic form) or indices (if it is in numeric form) of fixed exogenous variables. Specifying these obviates the necessity of having to fix the variances and covariances among these variables (and produces correct degrees of freedom for the model chisquare).

formula   a one-sided formula, to be applied to data to generate the variables for which covariances or raw moments are computed. The default formula is ~., i.e., all of the variables in the data, including an implied intercept; if a covariance matrix is to be computed, the constant is suppressed. In a multigroup model, alternatively a list one one-sided formulas as be given, to be applied individually to the groups.

robust   In sem: if TRUE, then quantities are calculated that can be used to compute robust estimates of coefficient standard errors and robust tests when the model is fit by multinormal maximum likelihood; the default is TRUE when the data argument is TRUE, and this option is only available when the data argument is given. In vcov: if TRUE, return a robust coefficient covariance matrix (if object contains the requisite information).

semmod   a semmod object containing the description of the model; optional, and normally supplied not directly by the user but via the semmod method for sem.

debug   if TRUE, some information is printed to help you debug the symbolic model specification; for example, if a variable name is misspelled, sem will assume that the variable is a (new) latent variable. Information about the optimization will also be printed, but details will vary with the optimizer employed. The default is FALSE.

...   arguments to be passed down, including from sem.default to the optimizer.

param.names   names of the t free parameters, given in their numerical order; default names are Param1, ..., Param$t$. Note: Should not be specified when the model is given in symbolic form.

var.names   names of the m entries of the v vector (typically the observed and latent variables — see below), given in their numerical order; default names are Var1, ..., Var$m$. Note: Should not be specified when the model is given in symbolic form.

analytic.gradient

    if TRUE (the default, except for the objectiveFIML objective function, where, at present, an analytic gradient slows down the computation), then analytic first derivatives are used in the maximization of the likelihood if the optimzer employed will accept them; otherwise numeric derivatives are used, again if the optimizer will compute them.

warn   if TRUE, warnings produced by the optimization function will be printed. This should generally not be necessary, since sem prints its own warning, and saves information about convergence. The default is FALSE.

maxiter   the maximum number of iterations for the optimization of the objective function, to be passed to the optimizer.

par.size   the anticipated size of the free parameters; if "ones", a vector of ones is used; if
                "startvalues", taken from the start values. You can try changing this argument
                if you encounter convergence problems. The default is "startvalues" if the
                largest input variance is at least 100 times the smallest, and "ones" otherwise.
                Whether this argument is actually used depends upon the optimizer employed.

start.tol, tol if the magnitude of an automatic start value is less than start.tol, then it is set
                to start.tol; defaults to 1E-6.

optimizer   a function to be used to minimize the objective function; the default for single-
                group models is optimizerSem. Alternatives are nlm, which employs the stan-
                dard R optimizer nlm; optimizerOptim, which employs optim; and optimizerNlminb,
                which uses nlminb — or the user can supply an optimizer. For multigroup
                model, the default is optimizerMsem, and msemOptimizerNlm, based on nlm, is
                provided as an alternative.

objective   An objective function to be minimized, sometimes called a "fit" function in the
                SEM literature. The default for single-group models is objectiveML, which
                produces maximum-likelihood estimates assuming multinormality. An alterna-
                tive is objectiveGLS, which produced generalized least squares estimates —
                or the user can supply an objective function to be minimzed. For multigroup
                models, the default is available is msemObjectiveML for ML estimates and an
                alternative is msemObjectiveGLS for GLS estiamtes.

cls   primary class to be assigned to the result; normally this is not specified directly,
                but raither is inferred from the objective function.

ram   numeric RAM matrix.

object   an object of class "sem" or "msem", returned by sem.

standardized   if TRUE, return standardized coefficients.

analytic   return an analytic (as opposed to numeric) estimate of the coefficient covari-
                ance matrix; at present only available for the objectiveML objective function.
                The default is FALSE for this objective function if there are no more than 100
                parameters and FALSE otherwise.

group   for a multigroup model, the quoted name of the group variable; if the data
                argument is given, snd is a single data frame, then this should be a factor in the
                data set or a variable coercible to a factor, to be used to split the data into groups;
                otherwise, the name is arbitrary.

groups   a character vector giving the names of the groups; will be ignored if group is a
                factor in data.

start   if "initial.fit" (the default), start values for a multi-group model are com-
                puted by first fitting the intra-group models separately by group; if "startvalues",
                then start values are computed as for a single-group model. In some cases, the
                intra-group models may not be identified even if the multi-group model is, and
                then start="initial.fit" should not be used.

initial.maxiter
                if start="initial.fit" for a multi-group model, then initial.maxiter gives
                the maximum number of iterations for each initial intra-group fit.

Details

The model is set up using either RAM ("reticular action model" – don't ask!) notation – a simple format for specifying general structural equation models by coding the "arrows" in the path diagram for the model (see, e.g., McArdle and McDonald, 1984) – typically using the `specifyModel` function; in equation format using the `specifyEquations` function; or, for a simple confirmatory factor analysis model, via the `cfa` function. In any case, the model is represented internally in RAM format.

The variables in the v vector in the model (typically, the observed and unobserved variables, but not error variables) are numbered from 1 to m. the RAM matrix contains one row for each (free or constrained) parameter of the model, and may be specified either in symbolic format or in numeric format.

A symbolic `ram` matrix consists of three columns, as follows:

1. **Arrow specification:** This is a simple formula, of the form `"A -> B"` or, equivalently, `"B <- A"` for a regression coefficient (i.e., a single-headed or directional arrow); `"A <-> A"` for a variance or `"A <-> B"` for a covariance (i.e., a double-headed or bidirectional arrow). Here, `A` and `B` are variable names in the model. If a name does not correspond to an observed variable, then it is assumed to be a latent variable. Spaces can appear freely in an arrow specification, and there can be any number of hyphens in the arrows, including zero: Thus, e.g., `"A->B"`, `"A --> B"`, and `"A>B"` are all legitimate and equivalent.

2. **Parameter name:** The name of the regression coefficient, variance, or covariance specified by the arrow. Assigning the same name to two or more arrows results in an equality constraint. Specifying the parameter name as `NA` produces a fixed parameter.

3. **Value:** start value for a free parameter or value of a fixed parameter. If given as `NA`, `sem` will compute the start value.

It is simplest to construct the RAM matrix with the `specifyModel`, `specifyEquations`, or `cfa` function, all of which return an object of class `semmod`, and also incorporate some model-specification convenience shortcuts. This process is illustrated in the examples below.

A numeric `ram` matrix consists of five columns, as follows:

1. **Number of arrow heads:** 1 (directed arrow) or 2 (covariance).

2. **Arrow *to*:** index of the variable at the head of a directional arrow, or at one end of a bidirectional arrow. Observed variables should be assigned the numbers 1 to n, where n is the number of rows/columns in the covariance matrix `S`, with the indices corresponding to the variables' positions in `S`. Variable indices above n represent latent variables.

3. **Arrow *from*:** the index of the variable at the tail of a directional arrow, or at the other end of a bidirectional arrow.

4. **Parameter number:** free parameters are numbered from 1 to t, but do not necessarily appear in consecutive order. Fixed parameters are given the number 0. Equality contraints are specified by assigning two or more parameters the same number.

5. **Value:** start value for a free parameter, or value of a fixed parameter. If given as `NA`, the program will compute a start value, by a slight modification of the method described by McDonald and Hartmann (1992). *Note:* In some circumstances, some start values are selected randomly; this might produce small differences in the parameter estimates when the program is rerun.

The numeric `ram` matrix is normally generated automatically, not specified directly by the user.

For `specifyEquations`, each input line is either a regression equation or the specification of a variance or covariance. Regression equations are of the form

`y = par1*x1 + par2*x2 + ... + park*xk`

where `y` and the `xs` are variables in the model (either observed or latent), and the `pars` are parameters. If a parameter is given as a numeric value (e.g., 1) then it is treated as fixed. Note that no "error" variable is included in the equation; "error variances" are specified via either the `covs` argument, via `V(y) = par` (see immediately below), or are added automatically to the model when, as by default, `endog.variances=TRUE`.

Variances are specified in the form `V(var) = par` and covariances in the form `C(var1, var2) = par`, where the `vars` are variables (observed or unobserved) in the model. The symbols `V` and `C` may be in either lower- or upper-case. If `par` is a numeric value (e.g., 1) then it is treated as fixed. In conformity with the RAM model, a variance or covariance for an endogenous variable in the model is an "error" variance or covariance.

To set a start value for a free parameter, enclose the numeric start value in parentheses after the parameter name, as `parameter(value)`.

`sem` fits the model by calling the optimizer specified in the `optimizer` argument to minimize the objective function specified in the `objective` argument. If the optimization fails to converge, a warning message is printed.

The RAM formulation of the general structural equation model is given by the basic equation

$$v = Av + u$$

where v and u are vectors of random variables (observed or unobserved), and the parameter matrix A contains regression coefficients, symbolized by single-headed arrows in a path diagram. Another parameter matrix,

$$P = E(uu')$$

contains covariances among the elements of u (assuming that the elements of u have zero means). Usually v contains endogenous and exogenous observed and unobserved variables, but not error variables (see the examples below).

The `startvalues` function may be called directly, but is usually called by `sem.default`; `startvalues2` is an older version of this function that may be used alternatively; see the `startvalues` argument to `sem`.

Value

`sem` returns an object of class c(*objective*, `"sem"`), where *objective* is the name of the objective function that was optimized (e.g., `"objectiveML"`), with the following elements:

`var.names`	vector of variable names.
`ram`	RAM matrix, including any rows generated for covariances among fixed exogenous variables; column 5 includes computed start values.
`S`	observed covariance matrix.
`J`	RAM selection matrix, J, which picks out observed variables.
`n.fix`	number of fixed exogenous variables.

n	number of observed variables.
N	number of observations.
m	number of variables (observed plus unobserved).
t	number of free parameters.
raw	TRUE if the model is fit to a raw moment matrix, FALSE otherwise.
data	the observed-variable data matrix, or NULL if data are not supplied.
semmod	the semmod specification object for the model, if one was supplied; otherwise NULL.
optimizer	the optimizer function.
objective	the objective function.
coeff	estimates of free parameters.
vcov	estimated asymptotic covariance matrix of parameter estimates, based on a numeric Hessian, if supplied by the optimizer; otherwise NULL.
par.posn	indices of free parameters.
convergence	TRUE or FALSE, depending upon whether the optimization apparently converged.
iterations	number of iterations performed.
criterion	value of the objective function at the minimum.
C	model-reproduced covariance matrix.
A	RAM A matrix.
P	RAM P matrix.
adj.obj	robust adjusted value of the objective function; NULL if robust is FALSE.
robust.vcov	robust estimated coefficient covariance matrix; NULL if robust is FALSE.

For multigroup models, sem returns an object of class c("msemObjectiveML", "msem").

Warning

A common error is to fail to specify variance or covariance terms in the model, which are denoted by double-headed arrows, <->.

In general, every observed or latent variable in the model should be associated with a variance or error variance. This may be a free parameter to estimate or a fixed constant (as in the case of a latent exogenous variable for which you wish to fix the variance, e.g., to 1). Again in general, there will be an *error variance* associated with each endogenous variable in the model (i.e., each variable to which at least one single-headed arrow points — including observed indicators of latent variables), and a *variance* associated with each exogenous variable (i.e., each variable that appears only at the tail of single-headed arrows, never at the head).

To my knowledge, the only *apparent* exception to this rule is for observed variables that are declared to be fixed exogenous variables. In this case, the program generates the necessary (fixed-constant) variances and covariances automatically.

If there are missing variances, a warning message will be printed, and estimation will almost surely fail in some manner. Missing variances might well indicate that there are missing covariances too, but it is not possible to deduce this in a mechanical manner. The specifyModel funciton will by default supply error-variance parameters if these are missing.

Examples

```
# Note: The first set of examples can't be run via example() because the default file
#  argument of specifyModel() and readMoments() requires that the model
#  specification and covariances, correlations, or raw moments be entered
#  at the command prompt. The examples can be copied and run in the R console,
#  however. See ?specifyModel and ?readMoments for further information.
#  These examples are repeated below using file input to specifyModel() and
#  readMoments(). The second version of the examples may be executed through example().

    ## Not run:

sem-deprecated   *Deprecated Functions in the sem Package*

Description

These functions are provided for compatibility with older versions of the **sem** package only, and
may be removed eventually. Although an effort has been made to insure backwards-compatibility,
commands that worked in versions of the **sem** package prior to version 2.0-0 will not necessarily
work in version 2.0-0 and beyond, or may not work in the same manner.

Usage

```
boot.sem(...)
mod.indices(...)
normalized.residuals(...)
path.diagram(...)
raw.moments(...)
read.moments(...)
specify.model(...)
standardized.coefficients(...)
standardized.residuals(...)
std.coef(...)
```

Arguments

```
...                    pass arguments down to replacements for deprecated functions.
```

Details

boot.sem is now a synonym for the [bootSem](#) function.

mod.indices is now a synonym for [modIndices](#).

normalized.residuals is now a synonym for [normalizedResiduals](#).

path.diagram is now a synonym for [pathDiagram](#).

raw.moments is now a synonym for [rawMoments](#).

read.moments is now a synonym for [readMoments](#).

specify.model is now a synonym for [specifyModel](#).

standardized.coefficients and std.coef are now synonyms for the [standardizedCoefficients](#)
and [stdCoef](#) functions.

standardized.residuals is now a synonym for [standardizedResiduals](#).

---

specifyModel   *Specify a Structural Equation Model*

Description

Create the RAM specification of a structural equation model.

Usage

```
specifyModel(file="", exog.variances=FALSE, endog.variances=TRUE, covs,
suffix="", quiet=FALSE)

specifyEquations(file="", ...)

cfa(file="", covs=paste(factors, collapse=","), reference.indicators=TRUE,
      raw=FALSE, ...)

multigroupModel(..., groups=names(models), allEqual=FALSE)

classifyVariables(model)

removeRedundantPaths(model, warn=TRUE)
## S3 method for class 'semmod'
combineModels(..., warn=TRUE)
## S3 method for class 'semmod'
update(object, file = "", ...)
## S3 method for class 'semmod'
edit(name, ...)

## S3 method for class 'semmod'
print(x, ...)
## S3 method for class 'semmodList'
print(x, ...)
```

Arguments

file	The (quoted) file from which to read the model specification, including the path to the file if it is not in the current directory. If `""` (the default), then the specification is read from the standard input stream, and is terminated by a blank line.
exog.variances	If `TRUE` (the default is `FALSE`), free variance parameters are added for the exogenous variables that lack them.
endog.variances	
	If `TRUE` (the default), free error-variance parameters are added for the endogenous variables that lack them.

covs   optional: a character vector of one or more elements, with each element giving a string of variable names, separated by commas. Variances and covariances among all variables in each such string are added to the model. For confirmatory factor analysis models specified via `cfa`, `covs` defaults to all of the factors in the model, thus specifying all covariances among these factors.

suffix   a character string (defaulting to an empty string) to be appended to each parameter name; this can be convenient for specifying multiple-group models.

reference.indicators

  if `FALSE`, the default, variances of factors are set to 1 by `cfa`; if `TRUE`, variances of factors are free parameters to estimate from the data, and instead the first factor loading for each factor is set to 1 to identify the model.

raw   if `TRUE` (the default is `FALSE`), a path from `Intercept` to each observed variable is added to the model, and the raw second moment for `Intercept` is fixed to 1. The `sem` function should then be called with `raw=TRUE`, and either supplied with a data set (via the `data` argument) or a raw-moment matrix (via the `S` argument).

quiet   if `FALSE`, the default, then the number of input lines is reported.

x, model, object, name

  An object of class `semmod` or `semmodList`, as produced by `specifyModel` or `multigroupModel`.

warn   print a warning if redundant paths are detected.

...   For `multigroupModel`, one or more optionally named arguments each of which is a `semmod` object produced, e.g., by `specifyModel`, `specifyEquations`, or `cfa`; if only one such model is given, then it will be used for all groups defined by the `groups` argument. If parameters have the same name in different groups, then they will be constrained to be equal. For `specifyEquations` and `cfa`, arguments (such as `covs`, in the case of `specifyEquations`) to be passed to `specifyModel`; for `combineModels`, `sem` objects; ignored in the `update` and `print` methods.

groups   a character vector of names for the groups in a multigroup model; taken by default from the names of the `...` arguments.

allEqual   if `FALSE` (the default), then if only one model object is given for a multigroup model, all corresponding parameters in the groups will be distinct; if `TRUE`, all corresponding parameters will be constrained to be equal.

Details

The principal functions for model specification are `specifyModel`, to specify a model in RAM (path) format via single- and double-headed arrows; `specifyEquations`, to specify a model in equation format, which is then translated by the function into RAM format; and `cfa`, for compact specification of simple confirmatory factor analysis models.

`specifyModel`:

Each line of the RAM specification for `specifyModel` consists of three (unquoted) entries, separated by commas:

1. **Arrow specification:** This is a simple formula, of the form `A -> B` or, equivalently, `B <- A` for a regression coefficient (i.e., a single-headed or directional arrow); `A <-> A` for a variance or

A <-> B for a covariance (i.e., a double-headed or bidirectional arrow). Here, A and B are variable names in the model. If a name does not correspond to an observed variable, then it is assumed to be a latent variable. Spaces can appear freely in an arrow specification, and there can be any number of hyphens in the arrows, including zero: Thus, e.g., A->B, A --> B, and A>B are all legitimate and equivalent.

2. **Parameter name:** The name of the regression coefficient, variance, or covariance specified by the arrow. Assigning the same name to two or more arrows results in an equality constraint. Specifying the parameter name as NA produces a fixed parameter.

3. **Value:** start value for a free parameter or value of a fixed parameter. If given as NA (or simply omitted), sem will compute the start value.

Lines may end in a comment following #.

specifyEquations:

For specifyEquations, each input line is either a regression equation or the specification of a variance or covariance. Regression equations are of the form

y = par1*x1 + par2*x2 + ... + park*xk

where y and the xs are variables in the model (either observed or latent), and the pars are parameters. If a parameter is given as a numeric value (e.g., 1) then it is treated as fixed. Note that no "error" variable is included in the equation; "error variances" are specified via either the covs argument, via V(y) = par (see immediately below), or are added automatically to the model when, as by default, endog.variances=TRUE.

Variances are specified in the form V(var) = par and covariances in the form C(var1, var2) = par, where the vars are variables (observed or unobserved) in the model. The symbols V and C may be in either lower- or upper-case. If par is a numeric value (e.g., 1) then it is treated as fixed. In conformity with the RAM model, a variance or covariance for an endogenous variable in the model is an "error" variance or covariance.

To set a start value for a free parameter, enclose the numeric start value in parentheses after the parameter name, as parameter(value).

cfa:

For cfa, each input line includes the names of the variables, separated by commas, that load on the corresponding factor; the name of the factor is given optionally at the beginning of the line, followed by a colon. If necessary, the variables that load on a factor may be continued across two or more input lines; in this case, each such line but the last must end in a comma. A variable may load on more than one factor (as long as the resulting model is identified, of course), but each factor may appear in only one input line (or set of input lines, if the variable list is continued onto the next line). If the argument reference.indicators=FALSE, the default, cfa will fix the variance of each factor to 1, and by default include covariances (i.e., correlations) among all pairs of factors. Alternatively, if reference.indicators=TRUE, then the factor variances are free parameters to be estimated from the data, and the first loading for each factor is set to 1 to identify the model. These two approaches produce equivalent models, with the same fit to the data, but alternative parametrizations. Specifying the argument covs=NULL implicitly fixes the factor intercorrelations to 0.

See sem and the examples for further details on model specification.

Other Functions:

classifyVariables classifies the variables in a model as endogenous or exogenous.

combineModels and removeRedundantPaths take semmod objects as arguments and do what their names imply.

The file input argument to the update method for semmod objects, which by default comes from standard input, is a set of update directives, one per line. There are five kinds of directives. In each case the directive begins with the directive name, followed by one or more fields separated by commas.

1. **delete:** Remove a path from the model. Example: delete, RSES -> FGenAsp

2. **add:** Add a path to the model. Example (the NA for the start value is optional): add, RSES -> FGenAsp, gam14, NA

3. **replace:** Replace every occurrence of the first string with the second in the variables and parameters of the model. This directive may be used, for example, to change one variable to another or to rename a parameter. Example: replace, gam, gamma, substitutes the string "gamma" for "gam" wherever the latter appears, presumably in parameter names.

4. **fix:** Fix a parameter that was formerly free. Example: fix, RGenAsp -> REdAsp, 1

5. **free:** Free a parameter that was formerly fixed. Example (the NA for the start value is optional): free, RGenAsp -> ROccAsp, lam11, NA

The edit method for semmod objects opens the model in the R editor.

Value

specifyModel, specifyEquations, cfa, removeRedundantPaths, combineModels, update, and edit return an object of class semmod, suitable as input for [sem](#).

multigroupModel returns an object of class semmodList, also suitable as input for [sem](#).

classifyVariables returns a list with two character vectors: endogenous, containing the names of endogenous variables in the model; and exogenous, containing the names of exogenous variables.

Examples

```
# Note: These examples can't be run via example() because the default file
#   argument of specifyModel() requires that the model specification be entered
#   at the command prompt. The examples can be copied and run in the R console,
#   however.

    ## Not run:
model.dhp <- specifyModel()
    RParAsp  -> RGenAsp, gam11,  NA
    RIQ      -> RGenAsp, gam12,  NA
    RSES     -> RGenAsp, gam13,  NA
    FSES     -> RGenAsp, gam14,  NA
```

```
      RSES     -> FGenAsp, gam23,  NA
      FSES     -> FGenAsp, gam24,  NA
      FIQ      -> FGenAsp, gam25,  NA
      FParAsp  -> FGenAsp, gam26,  NA
      FGenAsp  -> RGenAsp, beta12, NA
      RGenAsp  -> FGenAsp, beta21, NA
      RGenAsp  -> ROccAsp, NA,      1
      RGenAsp  -> REdAsp,  lam21, NA
      FGenAsp  -> FOccAsp, NA,      1
      FGenAsp  -> FEdAsp,  lam42, NA
      RGenAsp <-> RGenAsp, ps11,   NA
      FGenAsp <-> FGenAsp, ps22,   NA
      RGenAsp <-> FGenAsp, ps12,   NA
      ROccAsp <-> ROccAsp, theta1, NA
      REdAsp  <-> REdAsp,  theta2, NA
      FOccAsp <-> FOccAsp, theta3, NA
      FEdAsp  <-> FEdAsp,  theta4, NA

  model.dhp

  # an equivalent specification, allowing specifyModel() to generate
  #  variance parameters for endogenous variables (and suppressing
  #  the unnecessary trailing NAs):

  model.dhp <- specifyModel()
  RParAsp  -> RGenAsp, gam11
  RIQ      -> RGenAsp, gam12
  RSES     -> RGenAsp, gam13
  FSES     -> RGenAsp, gam14
  RSES     -> FGenAsp, gam23
  FSES     -> FGenAsp, gam24
  FIQ      -> FGenAsp, gam25
  FParAsp  -> FGenAsp, gam26
  FGenAsp  -> RGenAsp, beta12
  RGenAsp  -> FGenAsp, beta21
  RGenAsp  -> ROccAsp, NA,      1
  RGenAsp  -> REdAsp,  lam21
  FGenAsp  -> FOccAsp, NA,      1
  FGenAsp  -> FEdAsp,  lam42
  RGenAsp <-> FGenAsp, ps12

  model.dhp

  # Another equivalent specification, telling specifyModel to add paths for
  #  variances and covariance of RGenAsp and FGenAsp:

  model.dhp <- specifyModel(covs="RGenAsp, FGenAsp")
  RParAsp  -> RGenAsp, gam11
  RIQ      -> RGenAsp, gam12
  RSES     -> RGenAsp, gam13
  FSES     -> RGenAsp, gam14
  RSES     -> FGenAsp, gam23
  FSES     -> FGenAsp, gam24
```

```
FIQ      -> FGenAsp, gam25
FParAsp  -> FGenAsp, gam26
FGenAsp  -> RGenAsp, beta12
RGenAsp  -> FGenAsp, beta21
RGenAsp  -> ROccAsp,  NA,     1
RGenAsp  -> REdAsp,   lam21
FGenAsp  -> FOccAsp,  NA,     1
FGenAsp  -> FEdAsp,   lam42

model.dhp

# The same model in equation format:

model.dhp.1 <- specifyEquations(covs="RGenAsp, FGenAsp")
RGenAsp = gam11*RParAsp + gam12*RIQ + gam13*RSES + gam14*FSES + beta12*FGenAsp
FGenAsp = gam23*RSES + gam24*FSES + gam25*FIQ + gam26*FParAsp + beta21*RGenAsp
ROccAsp = 1*RGenAsp
REdAsp = lam21(1)*RGenAsp  # to illustrate setting start values
FOccAsp = 1*FGenAsp
FEdAsp = lam42(1)*FGenAsp

model.dhp

classifyVariables(model.dhp)

# updating the model to impose equality constraints
#  and to rename the latent variables and gamma parameters

model.dhp.eq <- update(model.dhp)
delete, RSES -> FGenAsp
delete, FSES -> FGenAsp
delete, FIQ  -> FGenAsp
delete, FParAsp -> FGenAs
delete, RGenAsp  -> FGenAsp
add, RSES       -> FGenAsp, gam14,  NA
add, FSES       -> FGenAsp, gam13,  NA
add, FIQ        -> FGenAsp, gam12,  NA
add, FParAsp    -> FGenAsp, gam26,  NA
add, RGenAsp    -> FGenAsp, beta12, NA
replace, gam, gamma
replace, Gen, General

---

standardizedCoefficients
                    Standardized Coefficients for Structural Equation Models

---

Description

These functions calculate standardized regression coefficients for structural equation models. The function stdCoef is simply an abbreviation for standardizedCoefficients.

Usage

```
standardizedCoefficients(object, ...)
## S3 method for class 'sem'
standardizedCoefficients(object, digits = getOption("digits"), oneheaded = TRUE, twoheaded = TRUE,
## S3 method for class 'msem'
standardizedCoefficients(object, ...)

stdCoef(...)
```

Arguments

object	an object of class sem or msem returned by the [sem](#) function.
digits	number of digits for printed output.
oneheaded	standardize path coefficients? Default is TRUE.
twoheaded	standardize variances and covariances? Default is TRUE.
...	arguments to pass down.

Value

Returns a data frame with the coefficients, labelled both by parameter names and by arrows in the path diagram for the model. The msem (multigroup) method computes and prints the standardized coefficients for each group; it does not return a useful result.

Tests   *Six Mental Tests*

Description

These data are from the SAS manual and consist of six mental tests for 32 students, with some missing data. The three x variables are intended to load on a verbal factor, and the three y variables on a math factor. The data can be used to illustrate the estimation of a confirmatory factor analysis model by multinormal full-information maximum-likelihood in the presence of missing data.

Usage

```
Tests
```

Format

A data frame with 32 observations on the following 6 variables.

x1 score on verbal test 1.

x2 score on verbal test 2.

x3 score on verbal test 3.

y1 score on math test 1.

y2 score on math test 2.

y3 score on math test 3.

tsls   *Two-Stage Least Squares*

Description

Fits a regression equation, such as an equation in a structural-equation model, by two-stage least squares. This is equivalent to direct instrumental-variables estimation when the number of instruments is equal to the number of predictors.

Usage

```
## S3 method for class 'formula'
tsls(formula, instruments, data, subset, weights,
na.action, contrasts=NULL, ...)
## Default S3 method:
tsls(y, X, Z, w, names=NULL, ...)

## S3 method for class 'tsls'
print(x, ...)
## S3 method for class 'tsls'
summary(object, digits=getOption("digits"), ...)
## S3 method for class 'tsls'
anova(object, model.2, s2, dfe, ...)

## S3 method for class 'tsls'
fitted(object, ...)
## S3 method for class 'tsls'
residuals(object, ...)
## S3 method for class 'tsls'
coef(object, ...)
## S3 method for class 'tsls'
vcov(object, ...)
```

Arguments

formula	model formula for structural equation to be estimated; a regression constant is implied if not explicitly omitted.
instruments	one-sided model formula specifying instrumental variables.
data	an optional data frame containing the variables in the model. By default the variables are taken from the environment from which tsls is called.
subset	an optional vector specifying a subset of observations to be used in fitting the model.
weights, w	an optional vector of weights to be used in the fitting process; if specified should be a non-negative numeric vector with one entry for each observation, to be used to compute weighted 2SLS estimates.
na.action	a function that indicates what should happen when the data contain NAs. The default is set by the na.action option.
contrasts	an optional list. See the contrasts.arg argument of [model.matrix.default].
y	Response-variable vector.
X	Matrix of predictors, including a constant (if one is in the model).
Z	Matrix of instrumental variables, including a constant (if one is in the model).
names	optional character vector of names for the columns of the X matrix.
x, object, model.2	
	objects of class tsls returned by tsls.formula, for anova containing nested models to be compared by an incremental F-test. One model should be nested in the other; the order of models is immaterial.

s2	an optional estimate of error variance for the denominator of the F-test. If missing, the error-variance estimate is taken from the larger model.
dfe	optional error degrees of freedom, to be specified when an estimate of error variance is given.
digits	number of digits for summary output.
...	arguments to be passed down.

Value

`tsls.formula` returns an object of class `tsls`, with the following components:

n	number of observations.
p	number of parameters.
coefficients	parameter estimates.
V	estimated covariance matrix of coefficients.
s	residual standard error.
residuals	vector of residuals.
response	vector of response values.
X	model matrix.
Z	instrumental-variables matrix.
response.name	name of response variable, or expression evaluating to response.
formula	model formula.
instruments	one-sided formula for instrumental variables.
